Conventional TDD (Test Driven Development) is a well known practice that has proved useful in recent years. After many years, the methodology has recently acquired some new dimensions thanks to the emergence of Continuous Integration (CI) services and web-based testing solutions (which allow developers to test their applications in a browser). Today these tools have become an integral part of the development process. In this article we will look at how they can be used for a more complete testing of applications. How does it work? Continuous Integration In the last few years, Continuous Integration (CI) services and continuous delivery (CD) have become a crucial part of development. Such services allow developers to build and deploy their applications in an automated manner. Developers can use them to test and debug their code on a daily basis. The most relevant aspects of continuous integration are: The user is anonymous, who simply registers and logs in. In order to begin building the application, the developer has to select the type of CI service. Such services provide an online repository of the project at the moment of registration. The server can then notify the developer if there are pending changes to the project. At any time the CI server checks the build status. This means that the CI server checks if there are any errors in the code that has been integrated into the

repository. It automatically rolls back the code if there are any issues. The CI server gathers build results and sends them to the project owner, who can then assess the status of the build and the results, and ask for revision if required. Continuous Delivery

The CI server also provides an option for continuous deployment, which is when the application is published to a test or production environment. Continuous delivery is an advanced form of continuous integration, where the CI server is constantly integrating the code into the application. The benefits of continuous delivery include the following:

- A slower build

Continuous delivery is beneficial for developers who build applications using a particular build platform. Continuous delivery allows them to receive more feedback from users about the results of the build. In this case, the build can be executed at a slower pace. This is possible due to the fact that CI services provide more feedback to the users about
